The Sea Floor

The Oceans

- cover ~72% of the earth's surface;
- have an average depth of ~3.8 Km, compared to ~840 m average height of the continents; and
- comprise <200 Ma old basaltic floor; but were plausibly created ~3.7 Ga ago;

Rift va

- Bathymetric, magnetic and stratigraphic profiles across the submarine ridges and rises tend to be symmetric.
- Ridge axes have the youngest rocks, high heat flow and seismicity.

Visit the US Geological Survey at <u>http://pubs.usgs.gov/pdf/planet.pdf</u> or the Marine Geology and Geophysics Division of National Oceanic & Atmospheric Administration's (NOAA) National Geophysics Data Center (NGDC) at the URL: <u>http://ngdc.noaa.gov/mgg/mggd.html</u>

Physiography of the Sea Floor

- Ocean floor comprises (a) continental margins and (b) deep ocean basins.
- Continental margins (a) can be active (i.e., seismic) or passive (i.e., aseismic); (b) comprise ~14% of ocean area, with ~750 m average depth; and (c) carry ~52% of all sediments (thickness:
- Deep ocean basins (a) cover ~85% of the ocean surface and (b) comprise (i) <u>abyssal seafloor</u> (~80% of ocean area, ~4.5 Km average depth, ~13% of all sediments averaging ~200 m in thickness); (ii) <u>ridges and rises</u> (e.g., the Mid-Atlantic Ridge, East Pacific Rise etc.): ~6% of ocean area, ~2.5 Km average depth, ~28% of world's sediments (thickness ~8 Km); and (iii) <u>deep sea trenches and island arcs</u>: ~1% of ocean area, ~6.5 Km average depth, ~1% (?) of all sediments.

This Postulate of Sea-Floor Spread

ascribes the forming of new ocean floor to continental rifting and incessant volcanism at the rifted margins — a process that creates spreading submarine ridges and rises.

200

Ma = millions of years

Deep sea trenches form, on this picture, when the converging sea floor edges collide.
The other notable features of the sea floor include aseismic rises, seamounts, guyots, and submarine canyons.
